<a href="#">Energy and Environment Laboratory</a>	<a href="#">Dr. Masaatsu AICHI</a>	<p>Current approaches to energy supply and consumption face problems such as climate changes and dwindling resources. The development of key technologies for saving energy, switching to renewable energy resources, and appropriate waste disposal is required. Our goal is to perform research that will contribute to the development of these technologies, especially by taking advantages of the characteristics of subsurface formations. For example, we study ways of developing a sustainable energy system, especially through hydrogeological and thermo-poro-mechanical modeling of geothermal heat pumps, geothermal power plants, and the geological sequestration of carbon dioxide.</p> <p>On the other hand, we also start to study how to adapt to global warming. Combining mitigation and adaptation is an attractive choice but it is not simple because one countermeasure possibly causes another environmental effects. For example, though the groundwater becomes more important water resource under changing climate, the overexploitation of groundwater possibly causes another environmental problem such as land subsidence, sea water intrusion in coastal area, so on. We try to predict and prepare for this kind of domino-like propagation to other environmental problems in advance.</p>	<p>water resource, groundwater, land subsidence, modeling, monitoring</p>	<p><b>Analysis of land subsidence caused by groundwater abstraction to design monitoring system for a groundwater management</b></p> <p>Land subsidence caused by groundwater abstraction has been a severe environmental problem in Asian coastal megacities. By strictly regulating the groundwater abstraction, the land subsidence in several cities in Japan ceased today. On the other hand, the groundwater becomes more important water resource under changing climate. In addition, the high groundwater pressure is harmful for the subsurface infrastructures. Then, the possibility to restart groundwater abstraction is becoming a matter of debate. However, it is essential to avoid the restart of land subsidence problem.</p> <p>Theoretically, it can be achieved by controlling the groundwater abstraction rate so that the effective stress does not exceed the preconsolidation stress. However, it is very difficult practically because of the heterogeneity in subsurface formations. The practical approach will be a gradual change of ground water abstraction rate with appropriate monitoring to check whether the plastic deformation occurs or not.</p> <p>Then, the questions are what kind of and how accurate monitoring system is required, and how we can interpret</p>

the monitored data. In this program, we try to answer these questions by analytical or numerical modeling for typical hydrogeologic settings.

The schedule is roughly planned as follows:

1st-2nd week: Introduction to land subsidence modeling and monitoring system.

3rd -4th week: Simulation and design of monitoring system.

"Supercritical fluid" refers to a fluid in which the material's critical points of temperature and pressure are being exceeded. Dramatic physical changes are possible depending on the operating conditions of the material. In particular, the ionic content and dielectric constant of supercritical water changes extensively based on temperature and/or pressure. As a result of this, it becomes possible to select a reaction based on one's objective: from an ionic atmosphere suitable for inorganic reactions, to one implementing the dissolving of organics, which is equivalent to a non-polar solvent.

Taking advantage of these properties, it is expected that this new, inexpensive, environmentally-friendly reaction medium will replace conventional organic solvents. Our laboratory has many research goals, covering a broad range of topics: Degradation of harmful waste products using the oxidation reaction in supercritical water, organic synthesis using solid catalysts, and synthesis of inorganic materials such as nanoparticles and polymers. In regards to all of these fields, by designing, analyzing, and controlling reactions based on a study of chemical reaction rate and reaction engineering, we are advancing extensive research, from fundamental research related to the chemical reaction of supercritical fluids, to the cultivation of new engineering application technologies.

**Organic synthesis using supercritical water as an environmental technology**

Supercritical water is a promising reaction medium for organic reactions because its solvent properties can be varied with the temperature and the pressure, and these properties affect reaction kinetics and mechanisms. The aim of this study is to propose a methodology which enables to control the reaction rate and the selectivity of organic synthesis reactions only with the change of temperature and pressure of supercritical water.

<p><a href="#">Environmental</a> <a href="#">Chemical Energy</a> <a href="#">Engineering</a> <a href="#">Laboratory</a></p>	<p><a href="#">Dr. Junichiro OTOMO</a></p>	<p>Development of environmental-benign energy devices and systems is a crucial issue in terms of energy saving and reduction of CO<sub>2</sub> emission. The research in Otomo laboratory focuses on electrochemical reaction, catalytic reaction and ionic conduction in solid electrolytes with the objective of integrating the elemental technologies into new chemical energy conversion devices and systems such as fuel cells, hydrogen production and energy storage systems. The integration of physicochemical phenomena with different scales is necessary to construct novel energy devices and systems. Thus, we are investigating the physicochemical (or electrochemical) phenomena through the perspective in molecular-scale, mesoscopic scale and macroscopic scale to solve some energy problems.</p>	<p>Chemical looping, reversible fuel cell, hydrogen, energy storage, technology assessment</p>	<p>Hydrogen production and energy storage systems are key technologies in terms of future energy systems combined with renewable energy. Chemical-looping (CL) and reversible fuel cell (r-FC) technologies are efficient energy conversion systems, and they attract attention as next generation energy supply and storage systems. To advance the systems, their technology assessments are required as well as experimental studies. In this project, the assessment of environmental impact and relevant experiment for CL or r-FC system will be investigated based on physicochemical properties of component materials and reactions.</p>

<p><a href="#">Geosphere</a></p> <p><a href="#">Environment Systems</a></p> <p><a href="#">Laboratory</a></p>	<p><a href="#">Dr. Tomochika</a></p> <p><a href="#">TOKUNAGA</a></p>	<p>Underground geosphere environment has been extensively used to support highly developed human society; e.g., extraction of energy resources and groundwater, waste disposal, construction of tunnels and underground spaces. Because of these activities, environmental problems which affect the sustainability of our society have emerged. The target of our laboratory is to understand and predict the change of geosphere environment caused by human activities, and to develop necessary engineering measures to attain sustainable use of geosphere environment. Current research topics include, studying and evaluating geosphere environmental changes caused by energy resources development and proposing necessary technological measures for sustainable resources development, securing stable and safe freshwater resources and development of efficient management schemes, and modeling long-term fluid flow and material transport processes through geosphere and its application to waste disposal and energy resources exploration.</p>	<p>geosphere environment, coastal groundwater, natural resources management</p>	<p>Research topic: Analyzing natural and anthropogenic impacts on coastal groundwater systems by sandbox experiments and numerical simulations:</p> <p>About 70% of world's population live in coastal areas where groundwater is usually the primary source of freshwater. However, the freshwater-saltwater interactions in a coastal groundwater system is highly sensitive to variety of natural processes (e.g., tsunami disasters, climate change, tidal fluctuation, long-term transgression and regression) and human activities (e.g., groundwater abstraction, land reclamation, subsurface utilization). Understating the effects of natural and anthropogenic forcing on the dynamics of coastal groundwater systems can provide necessary information for the urban design/planning, sustainable managements of coastal resources, and protection of the coastal ecosystems.</p> <p>In this project, students will select one or several of natural/anthropogenic factors as the research target. The impacts of the selected factor(s) (e.g., tsunami disasters) on coastal groundwater systems will be studied by both laboratory sandbox experiments and numerical modelling. If necessary, field survey will be included in the activity. Students can obtain knowledge on the coastal hydrogeology, hands-on experience on building and operating experimental system, and skills on the numerical modeling approaches.</p>
