		(2) The cell wall is an essential cellular component in yeast. The cell		(9) Application of image-based monitoring system for green
		wall is dynamic, because it undergoes remodeling during the cell		algal Haematococcus pluvialis (Chlorophyceae) cells
		cycle. We demonstrated that small rho type GTPase Rho1 is		during culture
		regulated by the progression of the cell cycle. We also found that		

there is a new cell cycle checkpoint mechanism called "cell wall integrity checkpoint" which functions to control cell cycle progression in response to cell wall perturbation. We are now studying such signaling mechanism as well as biosynthesis of the cell wall in yeast. (3) Autophagy is a major pathway of bulk degradation of cytoplasmic materials. In yeast, autophagy has been studied as a cellular response for survival during nutrient-limited conditions. During autophagy, cytoplasmic components are enclosed in a membrane compartment, called an autophagosome. We are now studying the mechanisms of autophagosome formation and its degradation. Moreover, we have a particular interest in physiological significance of autophagy. Kawamura Laboratory Prof. Shoit KAWAMURA Prof. Shoit KAWAMURA By using non-model organisms to explore genetic variation and its ecological correlates in wild populations, it is now possible to reevaluate the evolutionary significance of human genetic variation. The evolutionary diversity of sensory systems—the visual system in particular-is an excellent model case for addressing these questions because recent technical developments have enabled functional evaluations. We all the single-locus L/M opsin gene on the X chromosome. We	1	1	I	1	<u> </u>
in response to cell wall perturbation. We are now studying such signaling mechanism as well as biosynthesis of the cell wall in yeast.
